BENIGN PAROXYSMAL POSITIONAL VERTIGO (BPPV)

By Sheelah Woodhouse, BScPT

WHAT IS BPPV?
Benign Paroxysmal Positional Vertigo (or BPPV) is the most common cause of vertigo, a false sensation of spinning.¹

- Benign – it is not life-threatening
- Paroxysmal – it comes in sudden, brief spells
- Positional – it gets triggered by certain head positions or movements
- Vertigo – a false sense of rotational movement

Fig. 1: Inner ear anatomy. Otoconia migrate from the utricle, most commonly settling in the posterior semicircular canal (shown), or more rarely in the anterior or horizontal semicircular canals. The detached otoconia shift when the head moves, stimulating the cupula to send false signals to the brain that create a sensation of vertigo. © Vestibular Disorders Association. WHAT HAPPENS DURING A BPPV EPISODE?
BPPV is a mechanical problem in the inner ear. It occurs when some of the calcium carbonate crystals (otoconia) that are normally embedded in gel in the utricle become dislodged and migrate into one or more of the 3 fluid-filled semicircular canals, where they are not supposed to be. When enough of these particles accumulate in one of the canals they interfere with the normal fluid movement that these canals use to sense head motion, causing the inner ear to send false signals to the brain.

Fluid in the semi-circular canals does not normally react to gravity. However, the crystals do move with gravity, thereby moving the fluid when it normally would be still. When the fluid moves, nerve endings in the canal are excited and send a message to the brain that the head is moving, even though it isn’t. This false information does not match with what the other ear is sensing, with what the eyes are seeing, or with what the muscles and joints are doing, and this mismatched information is perceived by the brain as a spinning sensation, or vertigo, which normally lasts less than one minute. Between vertigo spells some people feel symptom-free, while others feel a mild sense of
imbalance or disequilibrium.

It is important to know that BPPV will NOT give you constant dizziness that is unaffected by movement or a change in position. It will NOT affect your hearing or produce fainting, headache or neurological symptoms such as numbness, “pins and needles,” trouble speaking or trouble coordinating your movements. If you have any of these additional symptoms, tell your healthcare provider immediately. Other disorders may be initially misdiagnosed as BPPV. By alerting your healthcare provider to symptoms you are experiencing in addition to vertigo they can re-evaluate your condition and consider whether you may have another type of disorder, either instead of or in addition to BPPV.

WHERE SHOULD I SEEK HELP?
Your family doctor may suspect BPPV from the symptoms you are describing, since it is very commonly triggered by things like rolling over in bed, getting in and out of bed, tipping the head to look upward, bending over, and quick head movements. However, they may or may not be familiar with the testing or treatment of BPPV, or may only be familiar with management of the most common form of BPPV but not the rarer variants. General practitioners typically refer patients to a medical professional specifically trained to deal with vestibular disorders, most commonly a vestibular rehabilitation therapist (typically a specially trained physical therapist, but occasionally an occupational therapist or audiologist) or an ENT (ear, nose & throat specialist) who focuses on vestibular disorders. Sadly, some doctors are not aware that highly effective treatment is available and tell patients that they just have to live with the condition and hope that it reduces or resolves on its own, which is not in line with best practice.

HOW IS IT DIAGNOSED?
Normal medical imaging (e.g. an MRI) is not effective in diagnosing BPPV, because it does not show the crystals that have moved into the semi-circular canals. However, when someone with BPPV has their head moved into a position that makes the dislodged crystals to move within a canal, the error signals cause the eyes to move in a very specific pattern,
The relationship between the inner ears and the eye muscles are what normally allow us to stay focused on our environment while the head is moving. Since the dislodged crystals make the brain think a person is moving when they’re not, it mistakenly causes the eyes to move, which makes it look like the room is spinning. The eye movement is the clue that something must be happening mechanically to move the fluid in the inner ear canals when it shouldn’t be.

The nystagmus will have different characteristics that allow a trained practitioner to identify which ear the displaced crystals are in, and which canal(s) they have moved into. Tests like the Dix-Hallpike or Roll Tests involve moving the head into specific orientations, which allow gravity to move the dislodged crystals and trigger the vertigo while the practitioner watches for the tell-tale eye movements, or nystagmus.

There are two types of BPPV: one where the loose crystals can move freely in the fluid of the canal (canalithiasis), and, more rarely, one where the crystals are thought to be ‘hung up’ on the bundle of nerves that sense the fluid movement (cupulolithiasis). With canalithiasis, it takes less than a minute for the crystals to stop moving after a particular change in head position has triggered a spin. Once the crystals stop moving, the fluid movement settles and the nystagmus and vertigo stop. With cupulolithiasis, the crystals stuck on the bundle of sensory nerves will make the nystagmus and vertigo last longer, until the head is moved out of the offending position. It is important to make this distinction, as the treatment is different for each variant.

**Fig. 2: The right Dix-Hallpike position used to elicit nystagmus for diagnosis. The patient is moved from a seated to a supine position with her head turned 45 degrees to the right and held for 30 seconds.**

**HOW IS IT TREATED?**

Though many people are given medication for BPPV, there is no evidence to support its use in treatment of this condition. In extremely rare circumstances, surgical options are considered. However, fortunately, in the vast majority of cases, BPPV can be corrected mechanically. Once your healthcare provider knows which canal(s) the crystals are in, and whether it is canalithiasis or cupulolithiasis, then they can take you through the appropriate treatment maneuver. The maneuvers make use of gravity to guide the crystals back to the chamber where they are supposed to be via a very specific series of head
movements called Canalith Repositioning Maneuvers. In the case of cupulolithiasis, they would utilize rapid head movement in the plane of the affected canal to try to dislodge the ‘hung-up’ crystals first, called a Liberatory Maneuver, and then guide them out as described above.

One maneuver that is used for the most common location and type of BPPV is called the Epley maneuver. However, that will not work for all presentations of BPPV. Often people have tried the Epley maneuver themselves or had it performed on them without success. Later assessment reveals that it is actually a different maneuver that should have been used, or that it is not BPPV at all. This is why caution should be used with self-treatment or with being treated by someone who is not fully trained in identifying the many different variants of BPPV and respective treatment maneuvers. Additionally, before testing or treating for BPPV, the healthcare provider should perform a careful neurological scan, evaluation of the neck, and other safety-related investigations to determine if certain elements of the procedure need to be modified or avoided. This is another strong reason for caution with self-treatment or treatment by a minimally trained healthcare provider.

**WHAT HAPPENS AFTER TREATMENT?**

Many studies have been done into the effectiveness of treatment maneuvers for BPPV, with results showing rates of resolution well into the 90% range by 1-3 treatments (the more rare cupulolithiasis or ‘hung-up’ variant can be a little more stubborn, as can BPPV that is the result of trauma). It is possible to have more than one canal involved, especially after trauma, in which case your vestibular therapist would typically have to correct them one at a time. You may be advised to avoid certain head positions for a few days following treatment. However, current research suggests that post-maneuver restrictions do not significantly affect outcomes. Even after the crystals are back in the correct chamber and the spinning sensation has stopped, people can often feel some mild residual sensitivity to motion and unsteadiness, so it is important to follow up with your vestibular therapist so that they can evaluate this and provide home exercise techniques that typically correct this promptly.

**WILL IT COME BACK?**

Unfortunately, BPPV is a condition that can re-occur periodically with long-term recurrence rates as high as 50% within 5 years, especially in those whose BPPV is related to trauma. If it seems to always reoccur in the same canal and if deemed safe, your therapist may teach you to perform a specific treatment maneuver on yourself. However, it can be challenging to perform the maneuver on one’s self, so many people prefer to return to their vestibular therapist to confirm that they are experiencing the same problem, and if so, determine which
maneuver is indicated and provide the appropriate treatment. There are other conditions that can mimic BPPV, and because there are so many different variants of BPPV, the maneuver that worked one time is not necessarily going to be the treatment that is indicated the next time.

CONCLUSION

BPPV is a common problem, and will be encountered more and more as our population ages. The impact can range from a mild annoyance to a highly debilitating condition, and can affect function, safety and fall risk. Fortunately, symptoms tend to decline over time as the brain slowly adjusts to the abnormal signals it is receiving, or because the condition spontaneously resolves. However, with a health care professional who is appropriately trained in the assessment and treatment of BPPV, most patients are pleased that their problem can be easily corrected so their world can stop spinning.

Did this free publication from VEDA help you?

Thanks to VEDA, vestibular disorders are becoming widely recognized, rapidly diagnosed, and effectively treated.

VEDA’s mission is to inform, support, and advocate for the vestibular community.

You can help! Your tax-deductible gift makes sure that VEDA’s valuable resources reach the people who can benefit from them most – vestibular patients like you!

JOIN VEDA TO DEFEAT DIZZINESS™
By making a donation of: ☐ $40  ☐ $75  ☐ $100  ☐ $250  ☐ $1,000  ☐ $2,500

Senior discounts are available; contact us for details.

Members receive a Patient Toolkit, a subscription to VEDA’s newsletter, On the Level - containing information on diagnosis, treatment, research, and coping strategies - access to VEDA’s online member forum, the opportunity to join V-PALS, a pen-pals network for vestibular patients, and more!

For healthcare professionals: Individual and clinic/hospital memberships are available. Professional members receive a subscription to VEDA’s newsletter, a listing in VEDA’s provider directory, co-branded educational publications for their patients, access to a multi-specialty online forum, and the opportunity to publish articles on VEDA’s website. For details, call (800) 837-8428, email info@vestibular.org or visit https://vestibular.org/membership.
